

# Types of Graphic Files

Most images you use will **pixelate** if you make them a lot bigger

This makes them blurry and not fit to be used

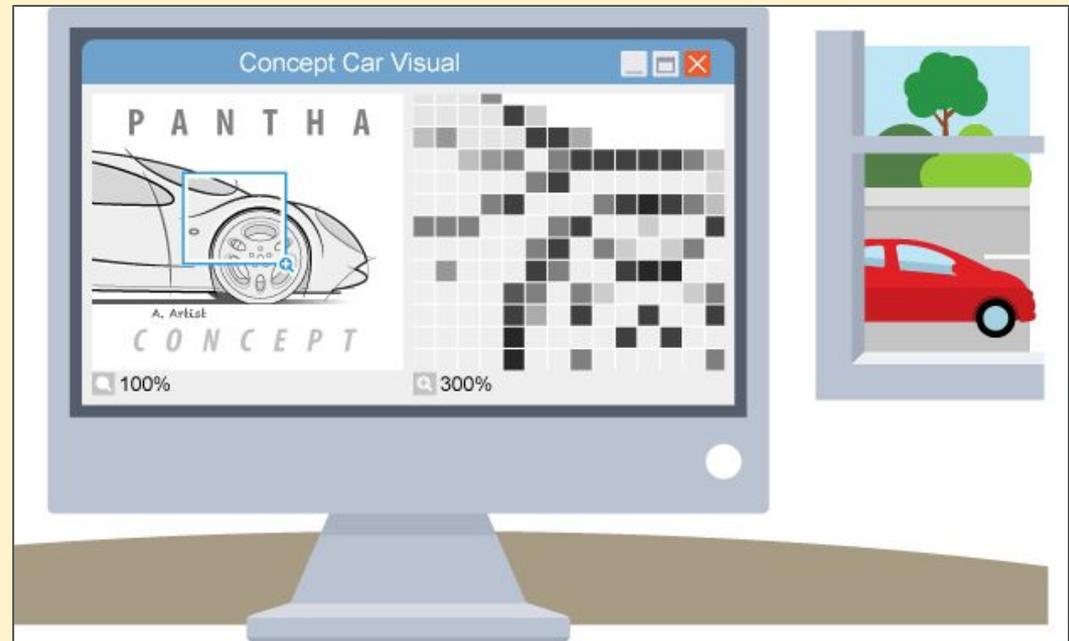

# Types of Graphic Files

Most image files are **Bitmap images**.

They are made up of **pixels**. Each image has a set number of pixels.

These include:

- **JPG** images
- **GIF** images
- **PNG** images

# Types of Graphic Files

**Bitmap images** are fine for most things.

The problem comes when you make them too big.

# Types of Graphic Files

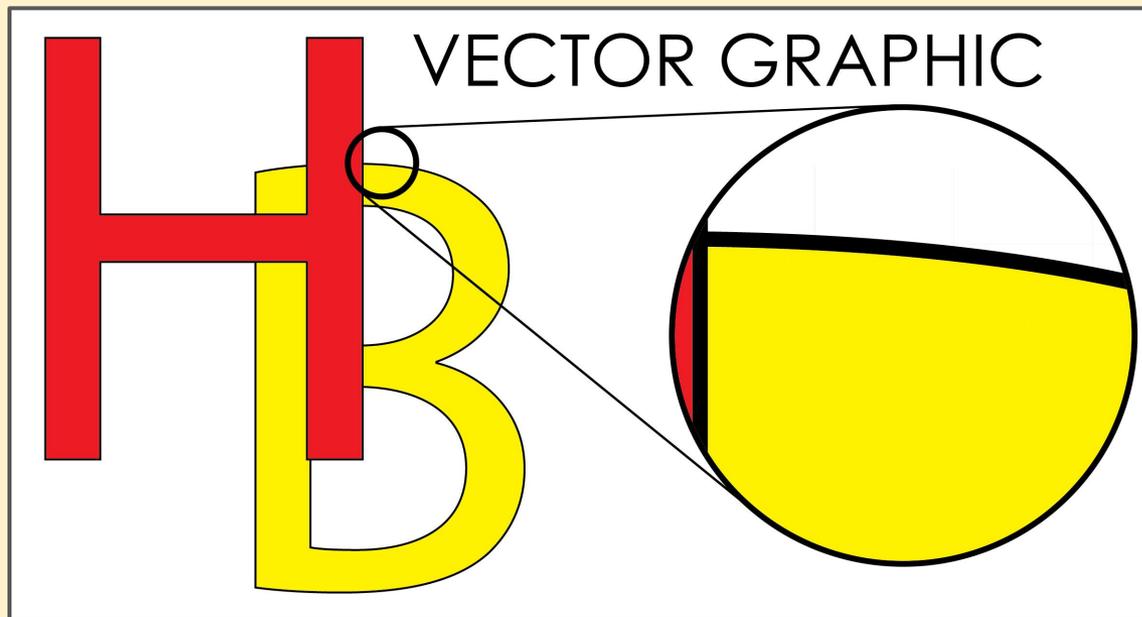

Some images need to be used at lots of different sizes.

Like logos.

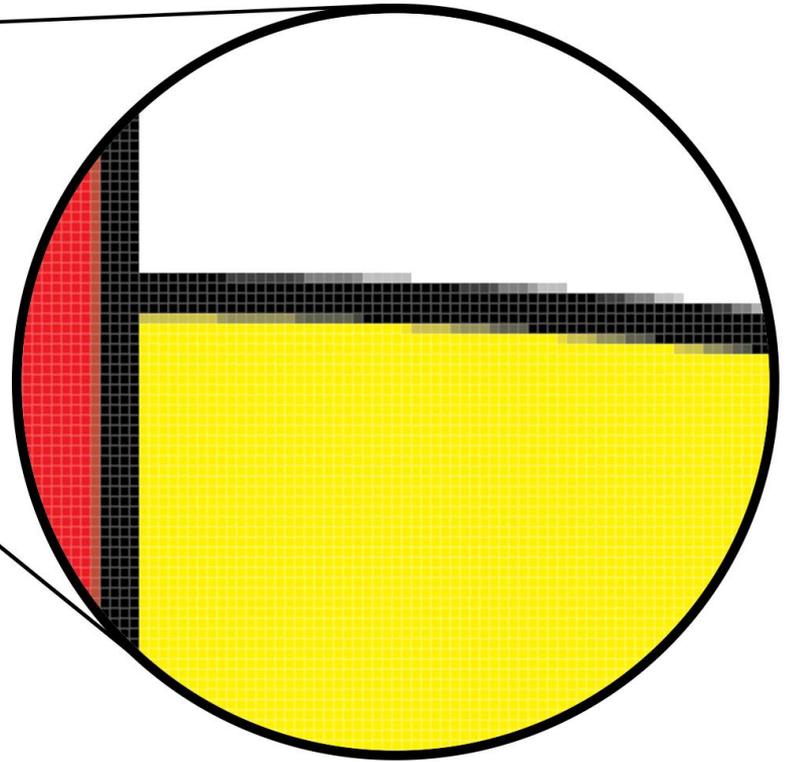

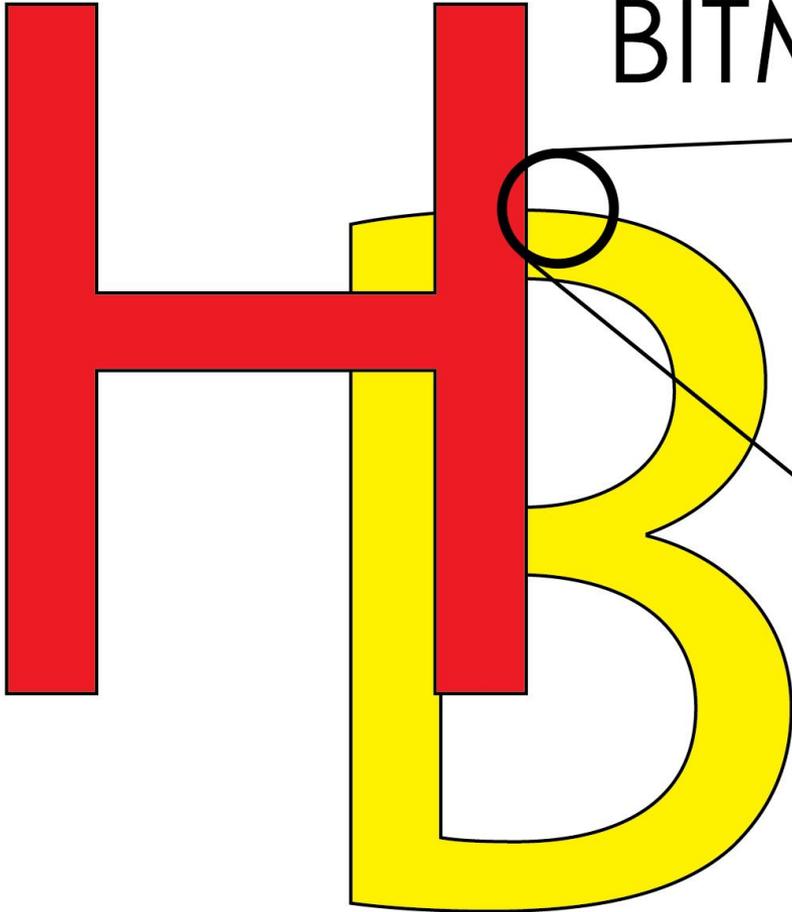

# Types of Graphic Files

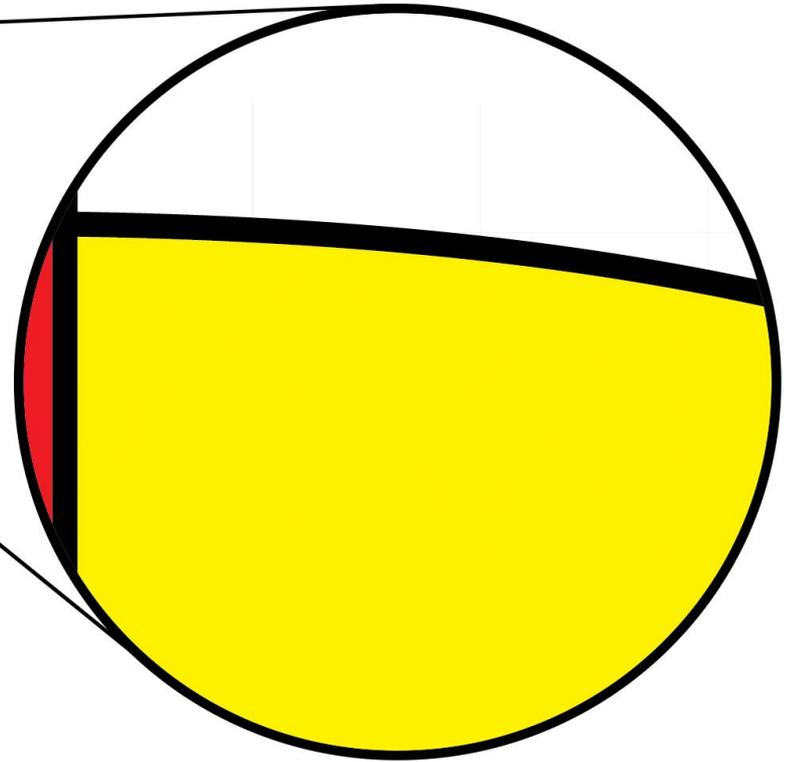

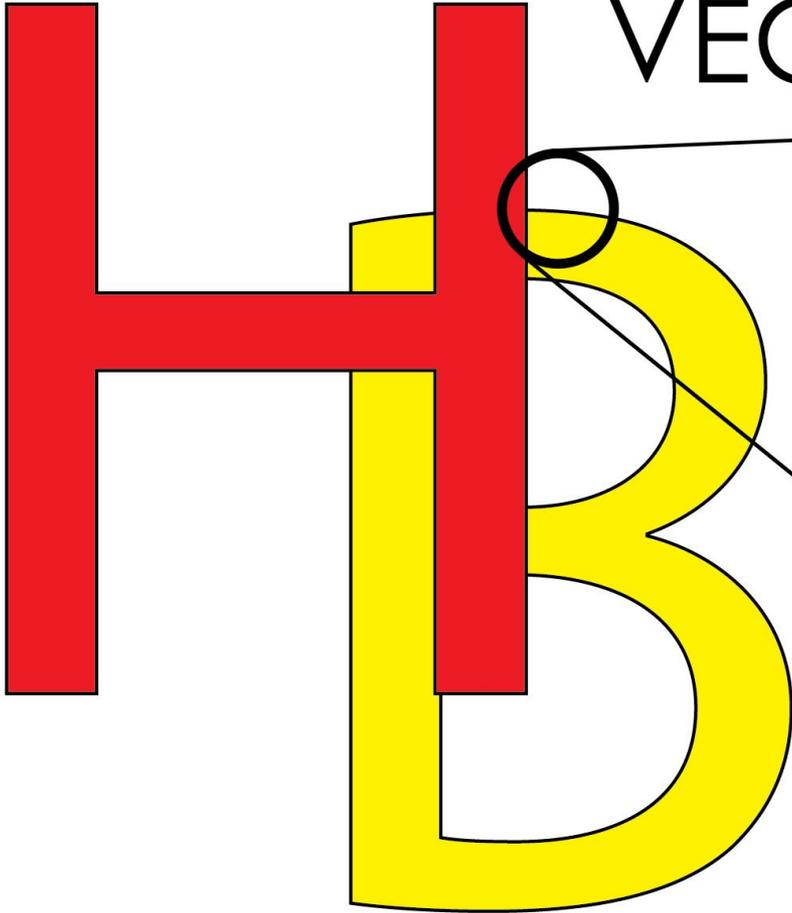

By creating the graphic as a **Vector Graphic File** Type we can resize the image as large (or small) as we want **without pixelation**

# BITMAP GRAPHIC

# VECTOR GRAPHIC

# Vector Graphics

Vector graphics work by using **mathematical formulae** to create shapes

This works great for images made up of shapes, lines, curves or font characters

It's rubbish for photographs

Saved as **SVG** (or **AI**) file format

Can be **rescaled** (resized endlessly)

# Vector Graphics
